

OIL THE DUTCH DISEASE AND THE TRINIDAD AND TOBAGO MACROECONOMY.

The Implications of oil prices and oil price volatility

Introduction

This research investigates the dynamic relationships between oil price shocks and the major macroeconomic variables in a small open oil-producing country Trinidad and Tobago.

The study extends the work of Lorde et.al. (2009) to include the unemployment rate, the historic maximum oil price reached in July 2008 followed by the global meltdown, the 2009 oil shock and the partial recovery of 2010.

Lorde et.al (2009) Results

Impulse response functions :

With positive oil price shock :

For the first two years output falls then grows positively throughout.

Positive response of gross investment, government consumption, and revenue, and price level.

Net exports exhibit signs of Dutch disease : sharp increase but by fourth year in deficit.

With positive oil price volatility shock :

Random swings to macroeconomy.

Smaller macroeconomic impacts on macroeconomy than shocks to oil prices.

Lorde et.al(2009) Results

Variance decompositions imply that the oil price is a major component of the chosen variables barring net exports and output.

Similar results but on a significantly smaller magnitude, concerning shocks to oil price volatility.

Causality from oil prices to output and oil prices to government revenue.

Government revenue granger causes net exports, government consumption and average prices.

Oil price behavior Lorde et al (2009) and post Lorde et al (2009)

Objectives of the study

- To highlight the vulnerability and dependence of the macroeconomy of T&T on oil prices and oil price volatility.
- To bring to the forefront the presence of the Dutch disease symptoms and the imperative of economic diversification within and away from the energy sector.

Econometric Methodology

- Nelson (1990) EGARCH

$$\gamma_t = \omega + \alpha_1 + \alpha_1 \gamma_{t-1} + \varepsilon_t, \varepsilon_t \sim N(0, \sigma_t^2)$$

$$\log(\sigma_t^2) = \omega + \beta_1 \log(\sigma_{t-1}^2) + \alpha_1 \left| \frac{\varepsilon_{t-1}}{\sigma_{t-1}} \right| + \gamma_1 \frac{\varepsilon_{t-1}}{\sigma_{t-1}}$$

- where γ_t is the log difference of oil prices. The estimated std ε_t dev. 1 is used to proxy oil price volatility. EGARCH (1,1) model is asymmetric ~~once~~ as there isn't the need to impose restrictions on the α, γ and β ; as opposed to the ARCH/GARCH the coefficient can be either positive or negative; the standard GARCH model assumes that negative shocks have the same impact as positive shocks of the same magnitude and allows for asymmetry.
- Innovation Accounting.
- Granger Causality Tests.

Impulse Response Analysis

A positive and significant response of output, gross investment, government revenue and consumption, the price level and the unemployment rate to a unitary shock in oil prices.

Dep var	period	output	ginv	rev	nx	cons	prices	ur
oilp	1	0.0089	0.0193	0.1326	1952.9	0.0324	0.0611	0.9314
	5	0.0268	0.1368	0.2423	1402.8	0.1347	0.0979	0.6360
	10	0.0297	0.1421	0.2422	1261.8	0.1437	0.0954	0.6468

Impulse Response Analysis

The impulse response functions suggest that an unanticipated rise in oil volatility brings about random swings in the macroeconomy. With regard to the magnitude of the responses, shocks to oil volatility tend to yield smaller macroeconomic impacts in comparison to shocks to oil prices.

Implications of the Analysis and Concluding Comment

Economic diversification must be the goal of whatever wise and prudent fiscal strategies and monetary policies are adopted by the policymakers of Trinidad and Tobago. Diversification of the economy not only brings about the benefits of insulating the macroeconomy from economic vulnerability but also the positive externalities of learning by doing, technological progress and innovation are fostered through a virtuous cycle of growth and development Velculescu and Rizavi (2005). The crowding out of the non booming (NB) export sectors by the booming export sector and non-traded goods sector can be prevented by the investment of oil windfalls towards economic diversification, which can mitigate the negative effects oil price volatility Weinthal and Luong (2006)

Implications of the Analysis and Concluding Comment

Policy makers in Trinidad and Tobago should bear in mind three points when formulating fiscal policy. Firstly, the non oil balance should feature prominently in the fiscal policy in the budget. Secondly, since aggregate demand can destabilize, exacerbate uncertainty and induce macroeconomic volatility.

Therefore, there should not be large swings in the fiscal policy as measured by the non-oil balance. Finally, oil wealth should be transferred to financial wealth. This implies viewing oil revenue more like financing rather than like income.

OIL, THE DUTCH DISEASE AND THE TRINIDAD AND TOBAGO MACROECONOMY

THANK YOU !
